

Pilot Rollout Plan

The rollout should begin with a controlled pilot among a small cohort of food merchants to validate recommendation accuracy, usability, and measurable business impact before scaling. Snoonu would select a representative group of marketplaces across different sizes and performance profiles, then enable the “Growth & Insights” dashboard in a safe, low-risk mode. Merchants can view their score breakdown, prioritized recommendations, campaign drafts, and the simulator, while high-impact actions such as pricing changes or aggressive discounting remain confirmation-only with conservative guardrails and clear explanations.

During this pilot, Snoonu would measure the north-star metric of merchant action adoption rate, defined as the percentage of system-generated recommendations that merchants implement. Supporting metrics would track whether adoption translates into real outcomes, including reductions in merchant-caused cancellations, improvements in fulfillment timeliness, changes in customer ratings and complaint rates, and increased participation in campaigns and sponsored tools. Alongside quantitative tracking, Snoonu should run lightweight qualitative check-ins with pilot merchants to confirm that recommendations are understandable, trustworthy, and easy to execute within their daily workflow.

Operationally, the pilot should also validate internal efficiency gains. Merchant Success teams can shift from manual performance monitoring to coaching driven by the platform’s automated insights, focusing their time on merchants who are struggling or showing high-risk signals. Support teams benefit from earlier detection of issues such as rising delays or cancellation patterns, enabling proactive intervention before problems escalate into customer tickets. Over time, this reduces repeated merchant training and reactive troubleshooting, lowering operational costs while improving consistency in the end-customer experience.

Once the pilot shows stable recommendation quality and clear performance lift, the platform should expand to the broader food merchant base in waves. This staged expansion allows Snoonu to tune scoring weights, thresholds, and recommendation triggers while keeping system behavior predictable at larger scale. Tier-based incentives, such as ad credits, visibility boosts, or priority support, should be introduced gradually only after the scoring system is validated and difficult to game, ensuring that incentives reinforce customer experience rather than encouraging short-term manipulation.

After achieving sustained adoption in food, Snoonu can repeat the same pilot-and-expand approach for grocery and then services, applying vertical-specific scoring weights and recommendation templates that reflect each category's realities. Grocery should emphasize stock accuracy, substitutions, and catalog quality, while services should emphasize SLA reliability, response speed, and scheduling consistency. As adoption grows, the platform can evolve from hourly or daily batch updates toward near real-time processing, and later add opt-in automation for low-risk actions such as generating campaign drafts or scheduling safe promotions within preset constraints. This phased rollout builds trust, increases self-serve advertising adoption, reduces cancellation-related support costs, improves merchant retention, and strengthens Snoonu's positioning as a long-term growth partner rather than a purely transactional platform.
